8	APPENDIX	13

# 2 General Description

For comfortable programming and control of the RSV, a country specific language setting is essential. From Version 8.1 on, it is possible to configure the command syntax in any language by means of a prescription for translation in the manner of a robot program. The only condition is that the signs resp. their input via keyboard can be represented on the PHG (teach pendant).

Texts or character strings can be:

- Programming orders
- Program names
- Macro names
- Macro parameters
- Variable names
- Comments in programs resp. macros
- Message texts
- Texts for system macros

The automatic translation function confines itself to translation of the command syntax and of the macro names. All additional texts have to be translated manually.

# 3 Target group

From level 3 - programmer

# 4 Safety instructions

The program sequence can be impaired by input mistakes in the configuration program "LEX". After the translation procedure, it must be ensured that the commands and macros work in the same manner as before.

# 5 Conditions: Hardware and Software

RSV Version 8.1 or higher / RobOffice Version 8.1 or higher. As of software version 10.0 the directory structure is modified for the files depending on language. Handling of language change-over was facilitated.

# 6 Installation/Configuration

The translation function always turns active if a change of the language with \_ILANGUAGE is done and the program "S:/\$CONFIG/\$CNF/LEX.MPR" with the translation prescription is available.

# 7 Programming

For a change of the language, there is required a translation prescription and change of the system variable \_ILANGUAGE. The prescription of the translation is included in the program "LEX" and has to be filed under the directory "S:/\$CONFIG/\$CNF" to be taken into consideration. Furthermore you need the following system variable for adjustment of the language:

### **ILANGUAGE** value 0

for "German" or

### ILANGUAGE value 1

for "foreign language".

\_ILANGUAGE is usually initialized in "S:/\$CONFIG/\$MAC/AUTOEXEC". After the change of the language setting, a restart of the control resp. of RobOffice/VRC is necessary.

# 7.1 STRUCTURE OF THE TRANSLATION PRESCRIPTION

In principle, the translation prescription is a robot program with a given structure. It is a main program and is filed under the name "LEX" in the path "S:/\$CONFIG/\$CNF". The program contains specific key words which are interpreted as a command for the translation to be made. Until now, the following key words have been used:

<Command> For identification of the section with the

robot commands

<Descriptor> For identification of the section with the

command descriptors

<Equate>

For identification of the section with the

system constants as a command parameter

<Macro>

For identification of the section with the

macro names

Fundamental structure:

MPR "LEX"

I < Command>

I (Command word in German);(Command word in foreign language)

I < Descriptor>

I (Descriptor in German); (Descriptor in foreign language)

I < Equate >

I (Constants in German); (Constants in foreign language)

I < Macro>

I (Macros in German); (Macros in foreign language)

**END** 

Keywords are defined in the I - step. The translation instructions are also contained in an I - step. The description in German and the description in the foreign language are separated by ",". No special characters such as "<Blank>" must occur in the translation instruction.

### Example:

MPR "LEX"

- I <Command>
- I ANA\_AUSG; ANA\_OUTP
- I ANA EING; ANA INP
- I ODER; OR
- I UND; AND
- I EXKL\_ODER; EXCL OR

```
I <Descriptor>
 I Nummer; Number
 I Muster; Pattern
 I Wurzel; Root
 I Ipo Dauer; Ipo Duration
 I Zeit; Time
 I Quelle; Source
 I <Equate>
 I #PASSIV; #PASSIVE
 I #AKTIV; #ACTIVE
 I #MOMENT AKTU; #MOMENT ACTU
 I #MOMENT_KONST; #MOMENT_CONST
 I #SCHLIESSEN; #CLOSE
 I #BIN; #BIN
 I <Macro>
 I TESTMAKRO; MACRO TEST
 I NOCHEINMAKRO; NEXT MACRO
END
```

The length of the individual terms must not be longer than 20 characters. Ambiguity has to be avoided. It is to be ensured that the allocation of the German terms to the foreign language terms is always clear.

Terms which are not included in the prescription of the translation will not be noticed. In this case, the original term is preserved.

A complete "LEX" program in the German - English version is contained in the appendix.

# 7.2 CHANGE OF THE LANGUAGE DEPENDENT ENTRIES

Change of the language for the robot programming language as well as for the macro names is exclusively done in the program "LEX" and through modification of the system variable ILANGUAGE.

The changes have to be exclusively made with the non-German text in the following way:

Example:

Selection of the command to be changed

I WERKZEUG; TOOL

Delete the non-German text

I WERKZEUG;

Insertion of the desired language (e.g. French)

I WERKZEUG; OUTIL

### Attention:

All entered terms such as command words, descriptors, equates and macros have to be clear. Macros must not be labeled like commands. The same applies to commands and macros each being listed one below the other.

### Example:

If the command "OR" is marked with "O" in a language (e.g. for the Spanish language), then it is identitical with the PLC-command "O" which has the same spelling in the German language as in the foreign language. This is **not allowed.** 

Anyway, the current command list for the allocation of names has to be considered. The current version is in the appendix.

Furthermore, it is to be mentioned that the generation or adaptation of the program "LEX" for RobOffice VRC is to be done. The use of a standard editor and the subsequent compiling with the external compiler (RRLC) can cause problems with the presentation of characters which are located in the enlarged IBM-character set (mutated vowels, accents etc.). A description of the character string used in the RSV is given in the documentation of the output and input command.

After a restart of the controller, the following things occur:

- the commands will be initialized internally in the control in the corresponding language.
- the command words in the files "S:/\$CONFIG/\$CNF/MENUCNFx" (x = 1..4) will be adapted and, if necessary, the macro calls in the programs will be translated and macro definitions (macro programs) will be renamed.

As of version 10.0 the MENUCNFx – files to be translated must be in the directory S:/\$CONFIG/\$CNF/FOREIGN.

- The language setting of RobOffice in the file "lang.lib" will be changed-over (German <-> English).

As of version 9.0 the file "lang.lib" for RobOffice is no longer of importance for language change-over. It is only required with use of the PC-tool "rrld.exe" and "rrlc.exe" that are included in the RobOffice package. The file "lang.lib" can be generated via the menu selection of the RobOffice VRC.

# 7.3 TRANSLATION PROCEDURE

The translation procedure will be accompanied by corresponding messages on the PHG:

Language conversion active!

Please wait!

Menucnf-files will be adapted!

Please wait!

Macros will be adapted!

Please wait!

### Language conversion finished!

The translation procedure may take several minutes which depends from the number of terms which have to be translated.

Especially with the translation of macros, in a greater amount the procedure may be prolonged.

Macro parameters will be defined in the definition head of the macro program itself. This definition head will not be considered by the translation program. The macro parameters will be maintained in the original language when called in a robot program.

Macro definitions in SKEYCNF resp. MENUCNFx at the time being are also not considered with automatic translation.

The files:

FKEYCNF1 ... FKEYCNF4,

SMSG\_CNF,

now as before have to be manually translated and to be read in to S:/\$CONFIG/\$CNF, the file

TXT\_FRMT

must be read in to S:/\$CONFIG/\$MAC.

As of version 10.0 the files FKEYCNF1 ... FKEYCNF4, SMSG\_CNF, SEYCNF1 ... SKEYCNF4, UKEYCNF1 ... UKEYCNF4 (if required) and also TXT\_FRMT must be stored in the directory S:/\$CONFIG/\$CNF/FOREIGN. Now as before they have to be translated by typing.

In case of need, comments, variable and program names have to be manually translated.

The reverse translation from the foreign language to German will be analog. The value of the system variable \_ILANGUAGE will be reset and the system will be restarted afterwards. The system internal language description will be initialized in German language. The programs MENUCNFx as well as the macro programs and macro calls in the programs will also be translated to the corresponding prescription in "LEX". All other language dependent programs have to be manually read in.

As of version 10.0 the other language-depending programs no longer need be read in anew. The programs are either in the directory S:/\$CONFIG/\$CNF/GERMAN and additionally in the directory S:/\$SYSTEM/\$SYSCNF. The files are only used from this directory, if the corresponding file is missing in the .../GERMAN directory.

It is important that the translation from German to a foreign language and the reversed translation are performed with **the same translation prescription** Only in this case, a clear language change-over is possible.

Therefore, the program "LEX" has absolutely to be saved (Backup / archival storage).

# 8 Appendix

Example of a complete "LEX"-program for translation from German to English and reverse.

# 2 General Description

With the automatic tool measurement the dimensions and the orientation of a tool mounted to the robot are to be determined.

With this information the robot control can refer the coordinates of the positions to be controlled to the tool tip (in short TCP from Tool Center Point)

As measurement by hand is very time consuming and is especially difficult for orientation and requires additional knowledge on the directions of the three coordinate axes at the robot flange, it should be performed automatically by the system.

Depending on the robot type and the number of its axes the robot has a different number of degrees of freedom. As of software version 10.0 the best possible method for determination of the tool data is derived from this.

Furthermore no additional measuring devices would be required for automatic tool measurement.

# 3 Target group

Setter

Service personnel

# 4 Safety instructions

For automatic tool measurement it is necessary to program positions very exactly. This means that the programmer stands in close proximity to the robot

Therefore it is mandatory to position the key switch at the portable teach pendant to "set" and not to "auto test".

# 5 Prerequisites: Hardware and Software

Functionality for automatic measurement of a tool is available as of software version 4.0.

For an exact tool measurement it is essential that the robot itself was measured exactly, otherwise there might occur inexact tool data or excess of internal monitoring limits with corresponding error message.

# 6 Operation

As of RSV-PCX version 12.0 the automated tool measurement has been extended.

It is now possible to determine the tool in two ways:

- manually by programming a calibration program and subsequently calling of the tool calibration (conventional method)
- automatically by starting an automated measuring sequence with the help of appropriate sensors (e.g. a light barrier).

# 6.1 MANUAL TOOL MEASUREMENT

Depending on the robot type and the number of grades of freedom resulting hereof, there are three possibilities how to determine many components of the tool:

- 6 degrees of freedom => complete determination of X, Y, Z, A, B, C
   (e.g. RV-kinematics)
- 4 or 5 degrees of freedom => Z component cannot be determined and must be entered subsequently by hand. (e.g. RL-kinematics with fourth axis as rotary axis or RL kinematics with 5 axes)
- 3 degrees of freedom => only the tool frame (orientation A, B, C of the tool) may be determined (e.g. RL-kinematics with 3 axes

Up to version 10.0 it was tried as a matter of principle to determine the tool completely. Especially with kinematics with less than 6 degrees of freedom errors could result.

As of version 10.0 the calibration mode of the control was selected using the machine data IROBOT\_TYPE\_E.

Now as before it is possible not to have all components determined but only part of these. For this purpose only those positions are programmed that are necessary for the requested calculation (refer to chapter ..).

# 6.1.1 Measuring program as of version 10.0

To perform the measurement a short program has to be generated first indicating the name of the tool variable (always starting with the letter "T" for "Tool", a segment with position steps for measurement of translational shares (X, Y, Z) starting with "I TRANSLATION" and one segment with 3 position steps for measurement of the rotatory shares starting with "I ROTATION". This program may be a main or a sub-program. The structure is as follows:

```
MPR "Program name"
VAR Name:T1
COPY source, Dest Var:T1
TOOL T1
    Determination of the positions for measurement of
the
    translational tool shares
C
    (standard measurement)
I TRANSLATION
POSITION 1
POSITION 2
POSITION 3
                (n <= 10)
POSITION n
    three further positions for measurement of the
    rotatory tool shares (on option)
C
    (extended measurement)
I ROTATION
POSITION n+1
POSITION n+2
POSITION n+3
END
```

In a.m. example the new calculated tool is deposited into tool variable T1.

After the control step "I TRANSLATION" minimum 4 and maximum 10 positions are programmed with a robot with 6 degrees of freedom, between 3 and 10 positions with a robot with less degrees of freedom. If no position was programmed, no translational measurement will be performed (the components X,Y and Z of the tool variable remain undetermined). In case more positions are programmed than the minimum quantity, then the tool calibration designates several results from the

combination with the number of positions required as a minimum and takes the mean. Thus a more precise result may be expected than with the minimum number of positions.

After the control step "I ROTATION" there are either three or no position steps at all. If no position step was programmed, no translational measurement will be performed (the components A, B and C of the tool variable remain undetermined).

# 6.1.2 Measuring program before version 10.0

For reasons of compatibility the old structure of the measurement program is supported, structure as follows:

```
MPR "Program name"
VAR Name:T1
COPY source:, Dest_Var:T1
TOOL T1
    Determination of the positions for measurement of
the
    translational tool shares
C
C
    (standard measurement)
POSITION 1
POSITION 2

Here the I-steps are missing and the number of the positions for translational measurement was fixed to 4. This program structure only supports robots with 6 degrees of freedom. For new generated measurement programs it should no longer be used.

# 6.1.3 Notes regarding programming of positions

Generating the measurement program, observe the following: The first n positions for calculation of the translational tool shares have to be programmed such way that the requested tool tip (the later TCP)

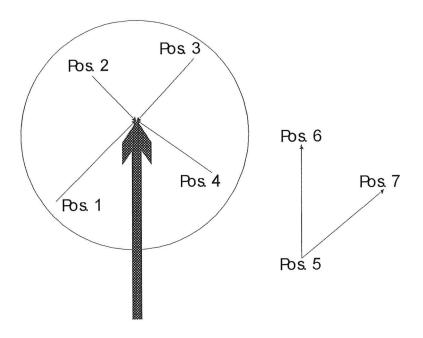

always points to the same place in space while the tool flange always is at different positions in space. Thus the tool flange for all n positions is at a surface of a sphere or on a circular plane for robots with less than 6 degrees of freedom) and the TCP is always on their centers. If the robot has less than 6 degrees of freedom (e.g. RL with 5 axes), it is not always possible to determine all components of the tool.

For maximum accuracy of the measurement it is necessary to select flange positions that are in a distance to each other as far as possible. In case the flange positions are too close to each other, the measurement will be interrupted with a corresponding error message. The minimum distance of the flange positions is adjustable via machine data RTOOLCALFACT. The data is a multiplication factor being multiplied with the calculated spherical radius and resulting in the minimum distance (standard setting of RTOOLCALFACT: 0.5). This factor will be applied unchanged if exactly the minimum number of positions is programmed. With each additional position it is reduced by 1/(n+1), n indicating the number of the additional positions. One additional position will result in the minimum required distance being divided in two, two additional positions will result in being divided in three etc.

The last three positions must have the same orientation. Modification of the orientation will result in an error message and in abort of the measurement. These last three positions indicate the axes directions of the tool coordinate system (in short TCS) and have to be set as follows: Position n+1 represents the origin of the TCS the vector between position n+2 and position n+1 the new X-axis the vector between position n+3 and position n+1 the new Z-axis. The two calculated vectors are orthogonalized internally starting from the new vector, that means, they will be aligned such way that the Z-vector stands on the X-vector in a 90° angle and the calculated Y-vector also shows a 90° angle towards the other two vectors. Minor inaccuracies during programming of these three positions are of no importance.

Illus. 1: Example with 7 positions for complete tool measurement

### 6.1.4 Start measurement

For starting the measurement in the FUNCT menu CALIB has to be selected and in the following menu "TOOL" has to be selected. The name of the calibration program generated earlier having been entered with the position steps, the calculation will be done and after the message "calibration terminated" the new tool variable will be provided. Same should be controlled for useful values with INFO VARIABLE "Tool variable".

# 6.1.5 Important machine data

Name: Significance:

RTOOLCALFACT Minimum distance of flange

positions

available as of version RSV

4.0

Default: 0.5

RTOOL VEC\_DIFF Max. vector difference of

individually calculated tool data

of calculation algorithm.

This machine data influences

the release of the "internal calculation error 519" or of error S495
Available as from version RSV 5.3
Default: 10.0 [mm]

### Remarks:

In the standard calculation a vector difference is built between the four programmed calibration positions and a calculated central point of the sphere. Four vectors are available as result, each describing the tool to be calculated. These four tool vectors vary from each other due to

- programming inaccuracies
- robot measurement inaccuracy
- or wrongly set machine data (observe reference point)

normally in [mm] range.

This **maximum vector difference** can be set using the machine data RTOOL\_VEC\_DIFF. The calculation algorithm exceeding this barrier, then the "internal calculation error 519" will result.

### ATTENTION:

Increase of the machine data on the one hand prevents the mentioned error message, but always points out to a wrongly set or badly measured robot.

# 6.2 AUTOMATED TOOL MEASUREMENT

The automated tool measurement is applicable since version 12.0. Essentially, it is configured as user program.

By means of suitable sensors (e.g. a light barrier switching very exactly and measuring in the coordinate system of the robot) this program searchs the geometrical dimensions of the tool used. The data determined is made available to the system software via a system variable. The tool variable to be calibrated is generated from this data.

### Limitations:

- The automated tool measuring only functions with complete kinematics, i.e. with robots with 6 main axes.
- The Z-direction of the tool to be measured must not lie resp. be laid parallel to the flange Z-direction.

# 6.2.1 Automatic TCP measurement prior to version 17.0

The user program has to determine the components X, Y and Z of the tool by means of appropriate search strategies. For further treatment later on, this data has to be copied to the system variable

RAUTOTOOLCAL\_TCP[3].

Doing so, the x-component of the tool must be stored in \_RAUTOTOOLCAL\_TCP[1], the y-component in \_RAUTOTOOLCAL\_TCP[2] and finally the z-component in \_RAUTOTOOLCAL\_TCP[3].

It is mandatory that the values of this system variable are available in the flange frame (calling the calibration command with control word 7, see chapter 6.2.3), i.e. these are the values that can be found after the calibration in the translatory part of the tool variable.

For determination of the tool orientation the tool has to be aligned parallel to the Z-direction of the calibrated sensor frame by means of searching for appropriate tool dimensions. This position is given to the control software in the system variable \_PAUTOTOOLCAL\_POS1.

In addition, the frame number of the sensor frame in the system variable \_IAUTOTOOLCAL\_FRAME, and the name of the tool variable to be calibrated in \_SAUTOTOOLCAL\_TOOL are required.

After all the required system variables have been inscribed with correct values, the calibration can be started. For starting the conversion, the control word of the command CALIBRATION is set to 7.

Please continue reading at chapter 6.2.3.

Due to the system this variant will not supply the correct tool orientation any way and therefore we recommend to change the tool calibration to the

new variant with a system update (see chapter 6.2.2).

# 6.2.2 Automatic TCP measurement as of version 17.0

As of version 17.0 the calibration regarding the handovers in the system variables behaves different than earlier.

The difference to the previous calibration on the one hand is the delivery of the calibration position in \_PAUTOTOOLCAL\_POS1. This position variable absolutely must be delivered in the sensor frame and includes a position of the tool being aligned in Z-direction of the sensor frame.

Since the position is absolutely delivered in the sensor frame, the use of the system variable \_IAUTOTOOLCAL\_FRAME is omitted at the same time. This variable is not evaluated any longer.

The contents of the system variable \_RAUTOTOOLCAL\_TCP[1 ... 3] no longer absolutely needs be delivered in the flange frame of the robot, but it is also possible to deliver the values in the sensor frame. The advantage is that all the calculations for determination of the TCP may be designed a little clearer.

The system software, however, must be informed about the data frame in \_RAUTOTOOLCAL\_TCP[] now. This happens when starting the calibration.

For starting the conversion from <code>\_RAUTOTOOLCAL\_TCP[]</code> the control word of the command <code>CALIBRATION</code> is set to "8".

In case the conversion must not happen, the control word of the command CALIBRATION is set to "7".

Please continue reading at chapter 6.2.3.

### 6.2.3 Call of the function

Execution of the calibration is started with the command

CALIBRATION Prog\_Name: "xxx", control word: 7

or rather

CALIBRATION Prog\_Name: "xxx", control word: 8

is started.

Here, only the command syntax needs the parameter "Prog\_Name". The name of any existing program may be entered (e.g. the name of the calibration program using the command).

The parameter "control word" must include the figure 7 or 8, in order to inform the system about the correct calibration mode.

With the control word 7 the translatory part delivered in \_RAUTOTOOLCAL\_TCP[3] is adopted into the tool variable without changes.

Beforehand, a transformation of the delivered tool vector from sensor frame into flange frame is made by means of the control word 8.

During calibration the following is determined:

- the tool-X-direction of the tool variable to be calibrated is vertical to the plane that is fixed by the sensor frame Z-axis and the flange Z-axis.
- the tool-Z-direction corresponds to the direction of the Z-axis of the sensor frame

The calibration command can be executed either through a macro or through the program sequence.

The necessary system variables represented in a table:

_RAUTOTOOLCAL_TCP[3]	X-, Y-, Z-component of tool calculated by the movement program
----------------------	--

_PAUTOTOOLCAL_POS1	the position aligned in the sensor frame by the movement program
_SAUTOTOOLCAL_TOOL	name of the tool variable to be inscribed
_IAUTOTOOLCAL_FRAME	frame number of the sensor frame (used only with calibration command with control word 7)

# 7 Error Messages/ Debugging

# 8 Appendix

# 8.1 THEORETICAL CONSIDERATION

Purpose of the tool measurement is to determine the dimension and the orientation of the tool and to enter these into a tool variable. In order to be able to interpret the importance of the variable contents it will be useful to know the axes of the coordinate system which are the basis of this variable:

The coordinate origin is on the flange plane in the center of the flange. The Z-axis points out of the flange, in the illustration below the X-axis shows horizontally to the rear (parallel to wrist axis) and the Y-axis shows to the bottom in a 90° angle hereof.

# Illus. 2: Representation of the tool coordinate systems

To explain this, it is possible to switch over the coordinate system with COORD KART TOOL and to run the directions with X+/X-, Y+/Y-, Z+/Z-.

After successful measurement the new tool variable will be available and can be checked by means of the variable display (keys <INFO>; <F4> (variable); enter the variable name directly up to 9.1, as of 9.2 select new variable with <F1> and then enter name). 6 values will be indicated, the first three will be length indications, the other three will be angles. These indications have to be understood such way that the work point

(see TCP in illus. 2)of the tool starting from the flange zero point will be shifted into X, Y and Z direction by the corresponding value (first three values) and afterwards turned by the indicated angle value round X, Y and Z. The values indicate a shifting and a rotation referred to the flange coordinate system (in short FCS).

It may be useful to roughly estimate the lengths and orientations of the tool prior to starting tool measurement and to enter these into the used tool variable. Therefore a short description of the commands for description of the tool variable will follow:

The variable type tool is - as already described - defined as follows in the ROBOTstarV:

- 1. X-shifting
- 2. Y-shifting
- 3. Z-shifting
- 4. Rotation around the x-axis of the FCS
- 5. Rotation around the y-axis of the FCS
- 6. rotation around the z-axis of the FCS

The following structure element names are derived from this for copying by components:

T-Var.X

T-Var.Y

T-Var.Z

T-Var.RX

T-Var.RY

T-Val.131

T-Var.RZ

As an example number constants are copied into a Tool variable:
